ALL TYPES OF

MACHINE LEARNING MODELS EXPLAINED

SUPERVISED LEARNING MODEL

A supervised learning model is trained using data that is already labeled with the correct answers. It is further classified into **Regression and Classification**.

Swipe →

UNSUPERVISED LEARNING MODEL

An unsupervised learning model is trained using data that is neither classified nor labeled, allowing the model to process the information without guidance. **Clustering, Self-Supervised Learning, and Auto-Encoding** are all types of unsupervised learning models.

Swipe →

REINFORCEMENT LEARNING MODEL

Reinforcement learning is achieved by interacting with an environment. It enables an agent to learn through trial and error using feedback from its own actions and experiences.

Swipe →

TRANSFER LEARNING MODEL

Transfer learning allows knowledge from previously learned tasks to be applied to new, related tasks. For example, knowledge gained from recognizing cats can help in identifying other animals.

Swipe →

MULTI-TASK LEARNING MODEL

Multi-task learning solves multiple tasks simultaneously by leveraging similarities between them and using a shared representation.

Swipe →

ENSEMBLE LEARNING MODEL

Ensemble learning improves overall model performance by combining predictions from multiple models. **Bagging** and **Boosting** are the most common ensemble techniques.
